	EAM115 A	36

## Special Absolute Encoders

<b>Absolute Singleturn Encoder for tool change</b>	EA40 T - U	42
<b>Absolute Explosionproof Encoder</b>	EAX80 A - D	44
	Elastic couplings	46
	Connectors	48
	Output configurations	50
	Installation and operation precautions	52

### Working principle

The working principle of an absolute encoder is very similar to the incremental one: a rotating disk, with transparent and opaque windows, interrupts a light beam acquired by photo receivers. Consequently, light pulses are converted into electric ones and then they are processed and transmitted by the output electronic.

### Absolute coding

The main difference between an incremental and an absolute is how they determine the position: the incremental determines the position from the zero index while the absolute bases its position on the output code, which is unique for each position inside the turn. Consequently, an absolute encoder never loses the real position neither if the power goes out nor in case of shifting.

Nonetheless, with an absolute encoder as soon as the power is restored the position is updated and immediately available instead, with an incremental encoder, the zero set would be required.

The output code is used to specify the absolute position. The first natural choice would be the binary code because it can be easily processed by external devices but the issue is that it is extracted directly from the rotating disc: acquiring the position synchronized with the output data can be difficult due to the simultaneous change of more than one bit.

For example, if two consecutive binary codes as 7 (0111) and 8 (1000) are considered, it can be noticed that the status of all bits changes. So, if the attempt to read the code in a specific time is made, it could be difficult to assure the correctness of the read data because there is more than one bit change in the same time. Therefore, a Gray code is used where only the status of one bit changes during two consecutive codes (even from the last to the first).

The Gray code can be easily converted to the binary by using a simple combinatory circuit (see tables above).

DECIMAL	BINARY	GRAY
0	0000	0000
1	0001	0001
2	0010	0011
3	0011	0010
4	0100	0110
5	0101	0111
6	0110	0101
7	0111	0100
8	1000	1100
9	1001	1101
10	1010	1111
11	1011	1110
12	1100	1010
13	1101	1011
14	1110	1001
15	1111	1000

## The Gray excess code

However, when the number of defined position is not a power of 2, even with the Gray code more than one bit can change simultaneously between the last and the first code value.

For instance, in a hypothetical 12 ppr absolute encoder, the code should be as the one shown in the aside. It is clear that between the positions 11 and 0 a 3 bit status simultaneous change may involve reading errors so that's not acceptable. The Gray excess code is used to maintain the typical one-bit variation specificity by making the 0 position corresponding to the N value. The N is a number that subtracted from the Gray code converted into binary provides the exact position value.

The formula to calculate the N value is:

$$N = \frac{2^n - IMP}{2}$$

Where: *IMP* IMP is the number of PPR  
 $2^n$  is the power of 2 multiple immediately higher than IMP

In our example N will be:

$$N = \frac{2^4 - 12}{2} = \frac{16 - 12}{2} = 2$$

POSITION	GRAY
0	0000
1	0001
2	0011
3	0010
4	0110
5	0111
6	0101
7	0100
8	1100
9	1101
10	1111
11	1110
0	0000

Error

POSITION	GRAY
0	0011
1	0010
2	0110
3	0111
4	0101
5	0100
6	1100
7	1101
8	1111
9	1110
10	1010
11	1011

Example: conversion of the position number 5

The Gray code of the position number 5 is 0100 which - converted into binary - is 0111 (7 in decimal). Subtracting from 7 the N value the real position value which is 7-2=5) will be obtained.

## Singleturn Absolute Encoders

A singleturn absolute encoder allows a precise acquisition of the angular position of the shaft to which the encoder is coupled to even if power goes out. Therefore, each single degree position is converted into a specific code (gray or binary) proportionally to the bit position. Eltra single-turn encoders can reach a resolution up to 8.192 ppr. (13 bit).

## Multiturn Absolute Encoders

The multiturn absolute encoder series is identified by the EAM prefix. This device allows a higher number of application representing such an interesting extension of the single turn encoder. This type of encoder presents a high single turn resolution (8192 ppr) and in the meantime it keeps count of the number of turns (up to 4096) representing so a significant linear extension maintaining flexibility according to customer specifications.

The encoder uses a main shaft to which one or more mechanical reducers are mounted in 'cascade' allowing a precise code reading even after a mechanical movement when the device is not powered.

Eltra's encoders are currently available up to 25 bit resolution equal to 33.554.432 positions. Safety and performances are among the highest in the market. Eltra's multiturn encoders are available with several electronic and mechanical output.

# PARALLEL INTERFACE GENERAL DESCRIPTION

## Parallel Interface

Parallel output is the standard one for singleturn absolute encoders mainly because it provides the data output in a 'bit by bit' way so there is basically a pin for each bit. However, this type of output is more burdensome for multiturn encoders when the bit number becomes high. Simply, just consider that a single turn encoder can have a resolution up to 13 bit while a multiturn can reach up to 25 bit. Moreover, in these bit numbers additional signals as count inversion and data output block (LATCH) have not been taken in consideration. So, the high number of signal outputs is the main reason for been introduced alternative transmission protocol as Serial Synchronized Interface (SSI) or field buses (PROFIBUS, CANBUS, etc.).

Output data in Gray format:

Output data can be available, depending on models, in both Gray and binary standard. In the latest encoder generation, the binary output is obtained by ASIC devices processing the Gray code signals coming from the photo-receiver circuit. However, in the binary code the correct output data issue is still intrinsically present due to the multiple bit status transitions between contiguous positions. In order to avoid this problem, in the past an output sync signal (STROBE) was used while the adoption of programmable logic overcame this limitation. Output data in binary format:

There are several output configurations to satisfy different electronic specifications requested from the controllers. Standard outputs are: NPN, NPN OPEN-COLLECTOR, PNP OPEN COLLECTOR, PUSH-PULL.

## Command inputs and optional outputs

As previously mentioned, external signals can control and command encoder output as reported below.

### STANDARD SIGNAL

- U/D: the encoder will increase the counting while the shaft rotates clock-wise. It is equivalent to rotate the encoder shaft in the opposite direction.

### OPTIONAL SIGNALS

(directly contact our offices for availability):

- LATCH: when connected, it maintains the current data as output. In this way, while the encoder shaft continues to turn, the output data doesn't change.
- RESET: it sets the zero position.
- STROBE: this signal is available only with binary code and indicates when it is possible to read the data. In fact, the logical status of the STROBE changes when the data is available (all bits have been updated).

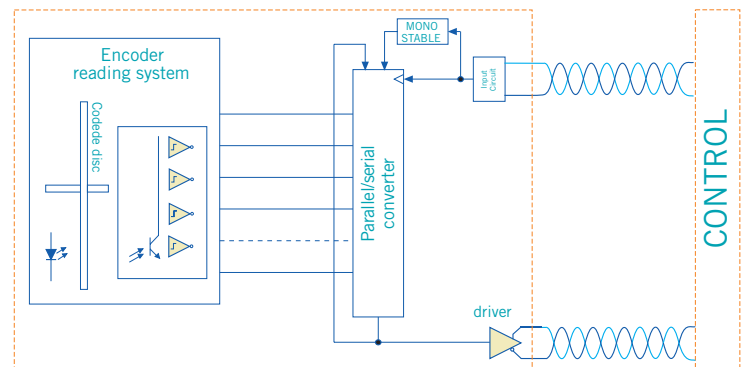

INPUT	HIGH STATE	LOW STATE
<b>U / D</b>	Inverts the code	No effect
<b>LATCH</b>	Blocks the code	No effect
<b>RESET</b>	Output reset	No effect

### Introduction

Evolution in automation is continuously growing and so its request for precision in measurement devices and consequently also in absolute encoder. To satisfy these demands, absolute encoders have been designed with higher and higher resolutions. However, higher precision means an increasing number of bits and consequently a growing need of wires. SSI interface was created in order to contain installation costs and to simplify wiring. This interface transmits data in a serial mode by using only two signals (CLOCK and DATA), independently from the precision of the encoder.

### Description

The SSI interface allows the transmission of the absolute encoder position data by a serial line synchronized by a clock. The following figure shows the block diagram of an encoder featuring an SSI interface:

The working principle of an encoder with an SSI interface is very similar to a standard one. Main parts are: a light source, a disc with transparent and opaque windows, photo-electric receivers, comparison/trigger circuits, a parallel/serial converter, a mono-stable circuit, an input circuit for the clock signal and an output driver for the data signal. The position data is obtained by the encoder reading system and continuously transmitted to a parallel/serial converter (based by a "shift register" with parallel loading). When the mono-stable circuit is activated by a clock signal transition, the data is stored and transmitted to the output synchronized with the clock signal. CLOCK and DATA signals are transmitted differentially (RS422) to enhance immunity from interference and to allow longer transmission distances.

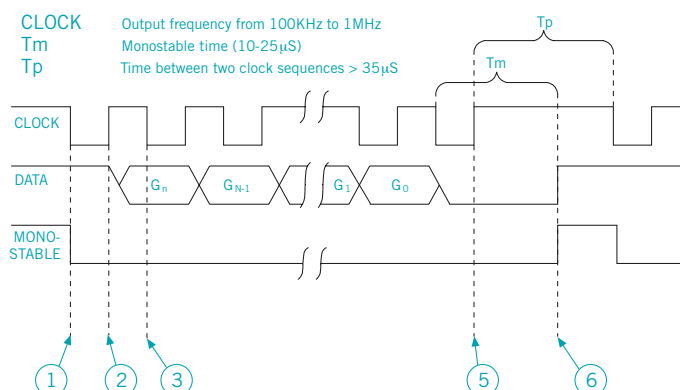

DATA signal circuit output

## Working Principle

When quiescent, CLOCK and DATA signals have a high logical status and the mono-stable circuit is disabled.

1. On the first CLOCK signal descent front, the mono-stable is activated and the parallel value at the P/S converter input is stored into the shift register.
2. On the CLOCK signal ascent front, the Most Significant Bit (MSB) is copied into the DATA signal output.
3. On the CLOCK descent front (when the signal is stable) the controller acquires the level value from the DATA signal and the mono-stable is re-activated.
4. On each further ascent front of the CLOCK pulse sequence, following bits up to the least significant one are copied in the DATA signal output and then acquired by the control on the descent front.
5. At the end of the CLOCK pulse sequence, when the external control has also acquired the value of the Least Significant Bit (LSB), the CLOCK pulse sequence stops and therefore the mono-stable is no longer re-activated.
6. Once the mono-stable time ( $T_m$ ) has elapsed, the DATA signal returns to a high logical status and the mono-stable disables itself.

## Transmission Protocol

The frame length of the transmitted data depends only on the encoder type (singleturn or multiturn) and not on the resolution. In fact, the standard frame length for a singleturn encoder is 13 bits, whilst for a multiturn one it is 25 bit. The MSB is in the center of the data, as shown by the below reported table:

T	2 <sup>n</sup>																													Ta		2 <sup>n</sup>	n

Number of turns

Singleturn

Multiturn

ppr

The transmitted frame format depends on the bit per turn and bit for turns encoder configuration.

**N** = number of bits per revolution  
**T** = number of bits for turns

$$T_a = T_m - \frac{T_c}{2}$$

**T<sub>c</sub>** = clock period

**T<sub>m</sub>** = monoflop time

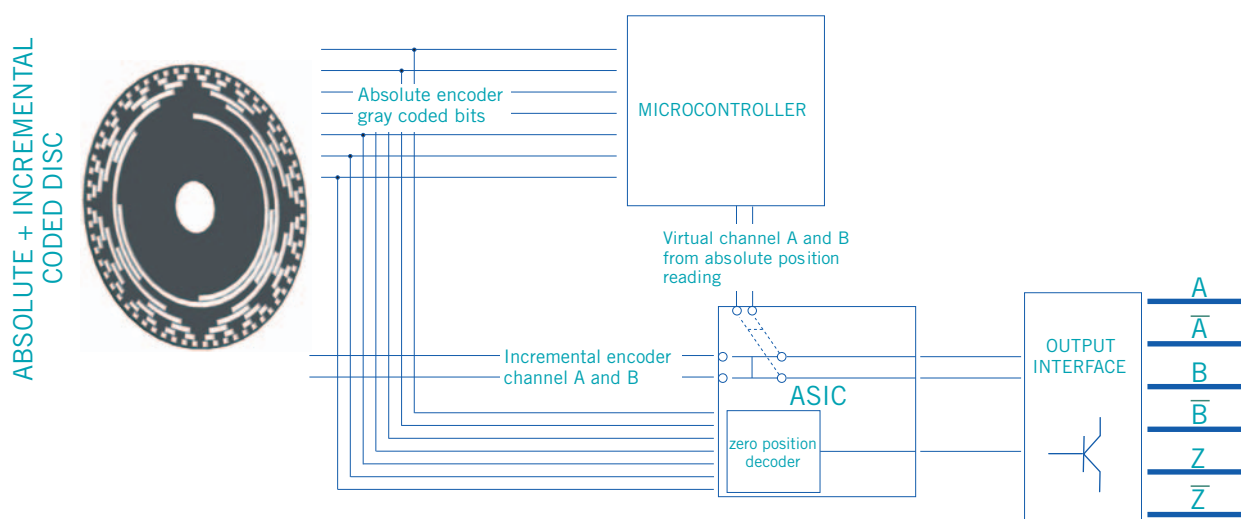

### Introduction

Absolute encoders with Incremental Code Output (ICO) combine, in a single product, advantages of both absolute and incremental encoders. ICOs are absolute encoders (they provide the absolute position within the single revolution) using the same output signals as incremental encoders. Main advantage of ICO encoders is – specially with high resolution – the number of wires because it is the same as an incremental encoder so substantially reduced compared to a standard absolute encoder. Moreover, as with incremental encoders, a simple counter is sufficient for reading the position instead of dedicated boards or multi I/O instruments.

### Description

From the reading system point of view, an ICO encoder is exactly made as a standard absolute one. Essentially the light beam is detected by photo-receivers and interrupted by a rotating disc with transparent and opaque windows. However, ICO encoders have a disc etched both with tracks for the absolute bit code and with tracks of an incremental encoder. Incremental output signals are out of 90 electrical grades one from the other and phased with the absolute code. The following figure shows the encoder block diagram:

Please note that a micro-controller handles encoder operations and initialization sequences. It also reads the absolute position and controls the ASIC device. The ASIC integrates a switch for A and B channels and a position decoder for the Z signal generation. Finally, the output interface converts the signals from the ASIC to the final electronic output signals.

## Working Principle

When the encoder is powered up, it goes into a stand-by state where A, B and Z channels are at a low logical level and the READ output is disabled. In this state the encoder does not work and any shaft rotation does not produce any effect on the output channel status.

To make the encoder working, it is necessary to activate the RESTART input for at least 50 ms. In this way the microcontroller managing the encoder reads the absolute position and then transmits a number of pulses equal to the absolute position detected by the A and B output channels. A pulse on the Z channel is transmitted before the position pulse sequence allowing in such way a zero setting of the counter.

When that pulse sequence is completed, the READY signal commutes to a high logical level and the counter has the absolute encoder position. Then, the micro-controller releases the control of A, B and Z channel outputs and the system managing the incremental encoder starts working. The described steps are called 'START-UP' sequence: when completed, the encoder is effectively ready to work.

## U / D

The U/D (Up-Down) input allows the inversion of the detected rotation direction represented by the increasing or decreasing the output data. By connecting this input to the power supply voltage, the count increases rotating the shaft clockwise. Vice versa, connecting U/D to the 0 V (or not connected), the output data value increases when the shaft rotates counterclockwise.

## RESTART

When the RESTART input is activated for at least 50ms the encoder executes the start-up sequence. It can be automatically executed when the power goes on, by permanently connecting the RESTART input to the power supply voltage.

## READY

The READY output indicates the encoder working status. When it has a low logical level, it means that the encoder is not functioning and so the RESTART input has to be activated. When the 'START-UP' is completed, the READY signal has a high logical level meaning the encoder is ready to work. The READY output also indicates any encoder malfunctioning due, for instance, to power supply interruptions or to internal faults. If it is continuously monitored, it can be used as a real alarm signal.

## SIGNAL TRACKING

If the encoder is moving at the beginning of the 'START-UP' procedure, i.e. due to vibrations or drive offset, the initial read position can be different when the transmission of the data as pulse sequence is completed. In order to avoid this situations, the encoder checks the absolute position value after the pulse sequence has been transmitted. If there is any difference, the encoder transmits again the absolute position until no difference is detected. Then the 'START-UP' stops and the READY output is activated. If variations in the position are quicker than transmissions, READY will not be activated.

## Resolution levels

ICO absolute encoders are available with a resolution up to a maximum of 1.024 ppr. The resolution is referred to the incremental output. In fact, a 1.024 ppr ICO encoder has a resolution equal to a 4.096 ppr of a standard absolute encoder. This is thanks to a x4 multiplication factor in the encoder reading device.

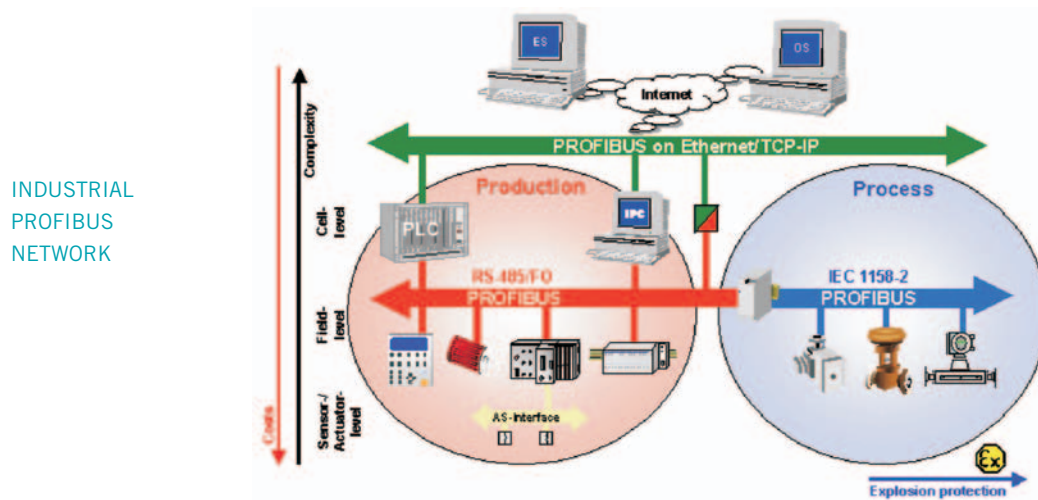

## Output configurations

Push-Pull and Line Driver output electronics are available. READY output is available only with Push-Pull electronic.

### PROFIBUS General Information

PROFIBUS (Process Field Bus) is a serial communications standard for devices connected to automation networks (field bus). It is an open protocol defined by the DIN 19245 that became European standard as EN 50170 volume 2. Profibus is promoted by Siemens and is widely diffused all over Europe. Thanks to the definition of three different communication profiles DP, FMS and PA, this field bus is suitable for many requirements in automation system. Starting with applications requiring a high cyclical exchange speed of a reduced number of bit (Profibus DP), up to the management of complex communications between “intelligent” devices (Profibus FMS) or tasks strictly related to automation process (Profibus PA). Hereinafter the attention will be focused on the DP version (decentralized periphery), which is the standard solution to manage devices by a bus. These devices usually are: I/O modules, sensors/transducers or actuators on a low level in automation systems.

### PROFIBUS DP characteristics

**NETWORK TOPOLOGY:** It is a common bus structure (closed on both sides) where up to 126 devices can be connected at the same time. If the physical support is an RS485 interface, up to 32 nodes can be inserted without using signal repeaters/re-generators.

**HARDWARE LEVEL:** In addition to the RS485 differential serial technology transmission, an optical fiber connection can be used. In any event, DP and FMS devices can co-exist in the same network. They share the same hardware interface communication (they are the same levels 1 and 2 of the ISO/OSI stack). The established standard requires an extremely accurate communication speed between 9.6 kBaud (min) and 12 kBaud (max).

**DEVICES PRESENT IN THE NETWORK:** It is possible to divide the devices into three classes: class 1 Master DP (DPM1), class 2 Master DP (DPM2) and Slave. The class 1 includes all the devices periodically exchanging information with distributed peripheral (they can directly manage the I/O network data with the other nodes, mainly slaves). The class 2 masters are designated to configure and to monitor network status and devices connected to it. Slaves have the task of directly exchanging information with the external word in both directions (in and out). Typical examples of slaves are: digital I/O, encoders, drivers, valves, different types of transducers, etc.

**BUS ACCESS METHODS:** Two configurations are available in a bus with single or multi master operating ways: the ‘Token Passing’ one, for exchanging information about network management among possible available masters, and the well known ‘polling interrogation’ for the master-slave communication.

## Main Functions:

The main characteristics implemented in the Profibus DP protocol are as follows:

**Periodic data exchange:** After the slave initialization step, every master is configured in order to exchange a maximum of 244 input bytes and 244 output bytes with every slave. The effective data exchange rate is based on the selected BaudRate, on the nodes present in the network and on the specific bus settings. Considering the maximum data exchange rate of 12 Mbaud, the Profibus DP is one of the fastest field buses.

**Synchronization:** Command controls are available (they are sent by the master in multicast). This gives the possibility to create a synchronous acquisitions through a slave, a group or all the slaves (Freeze Mode). Outputs sent to the slave have similar behavior. (Sync Mode).

**Parameterization and configuration security:** After a preset period of time - if the communication between the master/s and the slave/s is not repeated - the system goes into a safe status.

**Diagnostic functions:** Each slave can require to the master to be set up for reading its own diagnostic. In such way any possible problem occurring in the slave can be easily localized. The diagnostic can contain up to 244 bytes of information. Among them, the first six are mandatory for each DP slave.

**Dynamic slave management:** There is the possibility to activate or deactivate slaves present in the network. Moreover, it is possible to change by the bus slaves addresses that make possible this function.

**Easy network configuration:** Main characteristics of each device present in the network are listed in the form of a GSD file complying to Profibus specifications. This simplifies the set up and the configuration of the device by a graphic tools suitable for the purpose, such as the Siemens COM PROFIBUS software. As mentioned, the master-slave exchange data takes place periodically depending on the topology of the network and on the number of nodes present. However, before this step the slave has to be successfully parameterized and configured.

**Parameter setting:** The master sends to the slave a series of parameters necessary to specify its operation. The standard requires 7 bytes containing the mandatory information for the slave. Additional data can start from the eighth byte in the DU field (Data Unit, for more information see the Profibus DP) up to a maximum of 244 bytes for the communication frame.

**Configuration:** This step starts when the master has successfully set slave's parameters. During this step the master specifies the number and type of data, or better, the number of bytes to be exchanged with the slave both for incoming and outgoing information. This data is also present in the DU field of the communication frame: if the slave accepts the configuration, it can periodically exchange with the master.

**Periodic exchange:** The master specifies within the DU field frame the necessary information and the slave sends requested data within the reply frame. During periodic exchange, the slave may advise the master that a new diagnostic data is ready and then it asks to the master if it prefers reading this information in the next polling instead of the input data coming from the peripheral.

## Master-Slave Communication

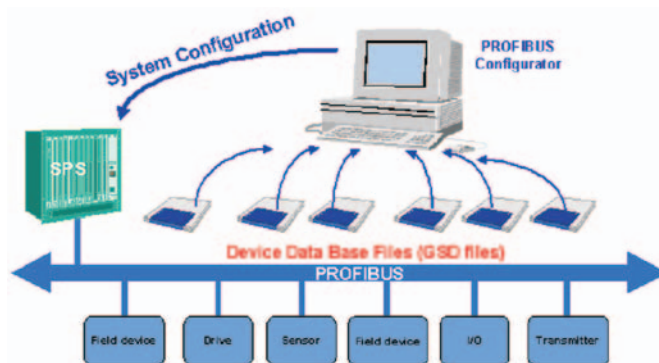

As already mentioned, the master-slave data exchange is periodic and essentially depends on the network topology and on the present node number. However, before starting the data exchange, it is necessary that slave parameter settings and slave configuration have been successfully completed. More details are as follows:

**PARAMETER SETTING:** During this step the master sends to the slave a series of operating parameters necessary for specifying its operation. The standard requires 7 bytes containing the mandatory information for the slave. Additional data can start from the eighth byte in the DU field (Data Unit, for more information see the Profibus DP) up to a maximum up to a maximum of 224 bytes.

**CONFIGURATION:** When the master successfully set slave parameters, the configuration process starts. Then, the master specifies the number and type of data represented from the incoming and outgoing bytes number which has to be exchanged with the slave. This data is also present in DU field; if the slave accepts the configuration, it will begin to periodically exchange data with the master.

**PERIODIC EXCHANGE:** The master specifies within the DU field frame the needed information and the slave will send requested data in the reply frame. During periodic data exchange the slave may advise the master that a new diagnostic data is ready and then it asks to the master if it prefers reading this information in the next polling instead of the input data coming from the peripheral.

## SINGLETURN ABSOLUTE ENCODER

### Absolute Encoder

Reduced dimensions absolute encoder.  
Main characteristics:

- Up to 256 ppr (8 bit) resolution
- Several output types available.
- Up to 28 Vdc input voltage.
- Output cable.
- Up to 6.000 rpm
- Up to IP66 sealing

### Ordering code

## SINGLETURN ABSOLUTE ENCODER

### Absolute Encoder

Ø50 absolute encoder. Main characteristics:

- Up to 1.024 ppr (10 bit) resolution.
- Several output types available.
- Up to 28 Vdc input voltage.
- Output cable with connector.
- Up to 6.000 rpm speed rotation
- Up to IP66 sealing

EA 50 A

# EA PARALLEL-SSI-ICO with PA 66 housing SINGLETURN ABSOLUTE ENCODER

## Absolute singleturn PARALLEL encoder description

Resolutions available up to 13 bit and 8.192 ppr. Wide application range thanks to several models and different flange types. This series assures high reliability even in the most tough industrial applications. It is available with cable connector output and protection class up to IP66. Gray and binary code output with several electronics available: NPN, NPN OPEN COLLECTOR, PNP and PUSH PULL. Please refer to the absolute output section.

## Absolute singleturn SSI encoder description

This series is designed to satisfy the new serial transmission philosophy of data output. A 13 bit word data is the standard output for these encoders. Meaningful bits are proportionally to the chosen encoder resolution. This type of transmission reduces wiring issues in order to maintain outstanding device performances. Only a four wire connection is needed: a pair for the position code and the other one for the clock signal, both transmitted with differential logic. In order to satisfy all dimensional requirements, a wide and complete range of mechanical parts is available.

## Absolute singleturn ICO encoder description

The only encoder available on the market featuring an absolute output with the simplicity of the incremental one and adding an easy wiring system. Thanks to the integration of a micro-controller, it provides all the advantages of an absolute encoder transmitting the data as an incremental one (A, B) with a transmission frequency between 0 and 10 kHz. As for Parallel and SSI series, a broad selection of mechanical configuration is available in order to assure an easy mounting according to customer requirements.

#### HOW TO MOUNT THE EA63G

- 1) Fix the antirotation pin on motor flange.
- 2) Couple the encoder shaft with the motor shaft, ensuring that the pin is inserted on the cave on the frontal part of the encoder (maintaining a minimum distance of 0,5 mm).
- 3) Fix the encoder shaft by the metal ring.

# EA PARALLEL-SSI METAL housing SINGLETURN ABSOLUTE ENCODER

## Absolute singleturn PARALLEL encoder description

Resolutions are available up to 13 bit and 8.192 ppr. Wide application range thanks to several models and different flange types. This series assures high reliability even in the most tough industrial applications. It is available with cable connector output and protection class up to IP66. Both Gray and binary code outputs are available with several electronic types: NPN, NPN OPEN COLLECTOR, PNP and PUSH PULL.

## Absolute singleturn SSI encoder description

This series is designed to satisfy the new serial transmission philosophy of data output. A 13 bit word data is the standard output for these encoders. Meaningful bits are proportionally to the chosen encoder resolution. This type of transmission reduces wiring issues in order to maintain outstanding device performances. Only a four wire connection is needed: a pair for the position code and the other one for the clock signal. Both signals are transmitted by differential logic. In order to satisfy all dimensional requirements, a wide and complete range of mechanical combinations are available.

EA PARALLEL-SSI

# EAM PARALLEL-SSI MULTITURN ABSOLUTE ENCODER

## Absolute multiturn PARALLEL encoder description

This series is designed for application where a very high precision is required, even also on extended linear distances. Resolutions up to 13 bits on the single turn (8,192 ppr) and 14 bits as number of turns (16,384 turns) are available. Sturdy mechanic parts and several flanges make this series suitable in such a wide range of applications assuring high performances even in the most tough industrial applications. This series is available with cable or connector output both with Gray or binary code. The PUSH PULL electronic is suitable for all industrial application fields.

## Absolute multiturn SSI encoder description

The absolute multiturn encoder series with SSI output provides data with the same format as previously described for singleturn encoders. Considering the high data volume in multiturn encoders, the serial data transfer is an efficient solution in order to curb the number of wires and the SSI standard is a valuable one.

The output data is a 25 bit word and useful bits are proportional to the resolution chosen for the encoder.

This transmission standard efficiently reduces wiring issues maintaining the highest level of performances. Similarly to singleturn encoders, number of wires for the transmission is 4 (2 for the data and 2 for the clock signal –both are transmitted in differential logic). A wide range of mechanical parts and flanges designed to satisfy different requirements is available.

## Connector or cable choice

According to the resolution and the chosen number of turns is possible to calculate the connections required by the connector or the cable. From the below table is possible to know the connection number.

### EXAMPLE 1:

256 PPR = 8 connections  
N° turns 32 = 5 connections  
Total connections = 13.

### EXAMPLE 2:

4096 PPR = 12 connections  
N° turn 4096 = 12 connections  
Total connections = 24.

From 1 to 13 connections a 16 poles cable or a 19 poles connector have to be considered.

From 14 to 25 connections a 32 poles cable or a 32 poles connector have to be considered.

If optional signals are used a cable or a 32 poles connector is suggested.

## PPR + Turns number

PPR	Bit number	Connections number
2	1	1
4	2	2
8	3	3
16	4	4
32	5	5
64	6	6
128	7	7
256	8	8
512	9	9
1024	10	10
2048	11	11
4096	12	12
8192	13	13

### HOW TO MOUNT THE EAM63G

- 1) Fix the antirotation pin on the motor flange.
- 2) Couple the encoder shaft with the motor shaft, ensuring that the pin is inserted on the frontal part of the encoder (maintaining a minimum distance of 0,5 mm).
- 3) Fix the encoder shaft by the metal ring.

### HOW TO MOUNT THE EAM63F

- 1) Couple the encoder shaft with the motor shaft.
- 2) Fix the spring at the motor flanges without screwing it.
- 3) Fix the encoder shaft by the metal gear.
- 4) Block the spring.

# EAM PROFIBUS MULTITURN ABSOLUTE ENCODER

## Presentation

The Eltra multiturn Profibus encoder series (Identification Number 0x0599) is complying to the Profibus DP standard as described on the European Standard EN 50170 Volume 2. Particularly, Eltra Profibus encoders are according to "PROFIBUS Profile for Encoders, Order No. 3.062". The Profibus DP interface maintains the same maximum resolution and characteristics (8.192 ppr and 4.096 revolutions) of the stand-alone version and adds the plus of the Profibus DP network.

By the Profibus DP network is possible:

- During the periodic data exchange, getting the indication of the angular position from the encoder.
- During the set up, setting the resolution as number of positions within the single turn and as number of turns.
- During the set up, changing the default increase direction count.
- To perform the PRESET operation (Set the encoder to read a specific position).
- Reading the diagnostic operating mode.
- Getting info about the code supplied by the device.

Directly from the device it is possible :

- To display the ON/OFF status.
- To display the device activity on the bus.
- Setting the device address
- If requested, inserting in the bus the termination resistance.
- Inverting the counting direction.

## Hardware installation device

Installing the Eltra Profibus encoder in a network requires the execution of the standard steps necessary for configuring any Profibus DP slave. The sequence of steps is as follows:

- 1 Commissioning the slave on the master (see corresponding paragraph).
- 2 Wiring the encoder into the Profibus network using or not terminations depending on the physical position the devices has in the bus
- 3 Directly set the address (which must be unique in the network and the same as the one chosen in point 1) for the slave.
- 4 Preparing the master side application/s and setting up the Profibus network.

On the back cover of the encoder (see picture) there is a led inspection window.

The device operating status can be controlled by the two led through the window. The green one shows the power presence and must be permanently switched on.

The red led switches off only during the periodic data exchange between the Profibus master and the encoder.

In the section plan alongside the 2 dip-switches of termination line and the 8 dip switches of device address are shown. In the particular shown configuration, the 2 termination line contacts are set to OFF so the termination of the bus is not expected to occur on the encoder.

Only seven out of the eight available dip-switches are used to address the slave because the maximum number of devices that can be connected to a Profibus network is 126. For addressing the device, only the first seven dip switches out of the eight available are used.

The contact number 8 is the LSB while the number 2 is the MSB.

The eighth contact (1) is used to invert the code.

## Connection to the network

For connecting Profibus encoders to the network, cables within the device can be accessed by the three skintops (in any event only two of them can be used).

Usually, a skintop is used for the connection to the bus, a second one to continue the network and the last one to eventually supply the power to the encoder (if the power supply is not available by the network in addition to the RS-485 twin wire).

## Terminal block access

To access the terminal block, unscrew the two screws on the rear plug and release the rear case from the main one by sliding it out from the sunken connector. Then, connect wires according to the diagram on the connector and as reported on the table on the right.

### Please NOTE:

To set and configure the slave into the Profibus DP master ('commissioning' step) it is necessary to use the "Exx\_0599.gsd" file delivered with the encoder. This file can eventually be downloaded from our following web site: [www.eltra.it](http://www.eltra.it).

## LED

## Network specifications

Usually, an A type cable is used to wire a DP/FMS network. This cable has to have the following characteristics:

Parameter	Cable type A
<b>Characteristics in <math>\Omega</math></b>	135 ... 165 at a frequency of (3...20 Mhz)
<b>Operating capacity (pF/m)</b>	< 30
<b>Loop resistance (<math>\Omega</math>/km)</b>	< = 110
<b>Core diameter (mm)</b>	> 0.64*)
<b>Core cross-section (mm<sup>2</sup>)</b>	> 0.34*)

This cable allows an optimum network utilization. In fact, it is possible to reach the maximum communication speed allowed (12 MBaud). However, there are some limitations due to the maximum physical dimensions of a bus segment as follows:

Baud rate (kbit/s)	Range/Segment
<b>9.6</b>	1200 m
<b>19.2</b>	1200 m
<b>93.75</b>	1200 m
<b>187.5</b>	1000 m
<b>500</b>	400 m
<b>1500</b>	200 m
<b>12000</b>	100 m

Finally, main physical and topographical specifications of a Profibus network are as follows:

Specifications	
<b>Maximum number of station participating in the exchange of user data</b>	DP: 126 (address from 0...125) FMS: 127 (address from 0...126)
<b>Maximum number of stations per segment including repeaters</b>	32
<b>Available data transfer rates in kbit/s</b>	9.6, 19.2, 45.45, 93.75, 187.5, 500, 1500, 3000, 6000, 12000
<b>Max. number of segments in series</b>	According to EN 50170, a maximum of 4 repeaters are allowed between any two stations. Dependent on the repeater type and manufacturer, more than 4 repeaters are allowed in some cases. Refer to the manufacturer's technical specification for details.

## DIP - SWITCHES setting

Below it is reported an example of the standard position of address and termination dip switches as well as settings for closing a Profibus line.

STANDARD  
SETTING

LINE  
OPEN

In this example the device address is set equal to 1001101 from bit number 2 to bit number 8 corresponding to HEX 77. Meanwhile, the first bit represents the inversion of the code (activated in this case).

# EA40 T/U

## ABSOLUTE SINGLETURN ENCODER FOR TOOL CHANGE APPLICATIONS

### Absolute Encoder

Ø40 T/U absolute encoders are specifically designed to be directly mounted on machine tools and they are suitable for being mounted on turrets for tool change (8 or 12 positions). The timing between encoder and turret can be overviewed by a led mounted on the enclosure. According to that it is possible to visualise the position of the first tool making easier and quicker the mounting for the operator.

Main characteristics:

- Easy mechanical mounting.
- Several output types available.
- 8 and 12 position turn configuration.
- IP66 sealing.

# PRECISION ELASTIC COUPLING

## Elastic Couplings

## Ordering code

ELTRA elastic precision couplings are essential parts for the transmission of rotational motion to the encoder shaft. Couplings are designed in aluminium alloy (type D11S A.A 2011) and are composed by a cylindrical body on which there is an helicoidal groove.

Main characteristics are:

- torsional rigidity;
- ability to support slight shaft misadjustments;
- ability to absorb small axial shift of the shaft.

ELTRA elastic couplings have also a perfect balancing of the rotating body. They don't have critical points subjects to breakage and are completely frictionless. Moreover, they perfectly transmit the rotation motion, even in case of axial misadjustment and misalignment. Our coupling do not require any type of maintenance. The internal drain allows the coupling between the shafts from a minimum of 0.5mm to a maximum of 6.12mm (note "F" quota).

NOTE: Elastic Coupling can be supplied with different coupling diameters. Eg: d1=8mm, d2=10mm. In this case the identification code should be: G25A8/10.

## Precautions against electrostatic discharges

Be sure the metallic connector is connected to the ground through a ring fixed to the screw of the connector itself. (Fig. 1)

Fig. 1

Ground connect to the shield and the connector case. (Fig. 2)

Fig. 2

For a better protection of the electronics against electrostatic discharges connect the metallic connector case to ground.

## Cable proper use

- Ensure a ground connection to the cable shield avoiding to connect it to the power ground.
- Keep the encoder cable (signal cable) to a proper distance from the power ones.
- Choose the cable's length according to installation requirements.
- Spread the cable avoiding spirals.

## News

- Cable extensions and connectors could be designed on demand.
- Testing on 100% of the production.
- Antivibration wiring system.
- **Contact us for further information.**

## NPN and NPN OPEN COLLECTOR electronic

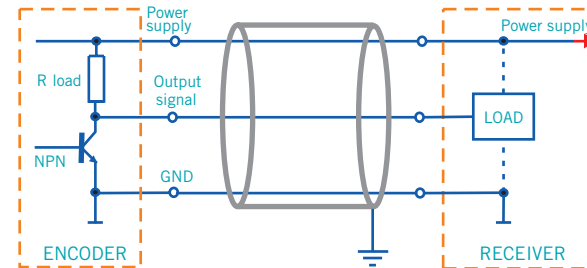

It is composed only by an NPN transistor and a pull-up resistor used to match the output voltage to the power supply when the transistor is quiescent. From the electrical point of view it is similar to TTL type logic and so it is considered compatible. If used correctly, it shows low saturation levels at 0 Vdc and close to 0 at the positive. It is proportionally influenced by the cable length, pulses frequency and by the load.

Please consider these specs for a proper use. The open collector variant is different for the lack of the pull-up resistor, freeing in such way the transistor collector from the tie of the encoder power supply allowing to obtain signals with different voltage.

## NPN OPEN COLLECTOR

## NPN

## PNP OPEN COLLECTOR

## PNP

## PNP and PNP OPEN COLLECTOR electronic

Main characteristics and limitations are the same as for NPN electronics. Main difference is the transistor, which is of PNP type and is constrained to the positive. The resistor, if present, is a pull-down one. Therefore, it is connected between the output and zero Vdc.

## PUSH-PULL

## PUSH-PULL electronic

Electronic featuring high performances. NPN or PNP major limitations are caused by the resistor, which works with a much higher impedance than a transistor. To overcome this issue, push-pull electronic uses a complementary transistor, so the impedance is lower for commutation to positive and to zero. This solution increases frequency performances allowing longer cable connections and an optimal data transmission even at high working speed. Saturation signals are low but sometimes higher than in NPN and PNP electronics. Anyway, PUSH-PULL electronics is in any case indifferently applicable instead of NPN or PNP.

## RS 422

## RS 422 electronic

LINE DRIVER is used when operating environments are particularly exposed to electrical disturbances or when the encoder is quite far from the receiver system. Data transmission and receiving work on two complementary channels so disturbances are limited (they usually come from other cables or close machinery). These interferences are known as «common way disturbances» as their generation is due to a common point: the system mass. Instead, in LINE-DRIVER transmitted and received signals work in «differential» way. In other words, it works basing the communication on voltage differences between complementary channels. Therefore it is not effective to common way disturbances. This type of transmission is used in 5 Vdc systems and it is also known as RS422 compatible. It is available with power supplies up to 24 Vdc.

## PROTECTIONS

## Protection for output stages

Two different kind of electronic protection against short circuits might be used: the passive one (using fuses, no linear resistors, etc.) and active one (using transistors). Eltra's encoders can be equipped with both type of protection against short circuits.

### Passive protection

Passive solution is the cheapest one. It is used to avoid accidental short circuits, which rarely happens. The component which carries out the protection is called PTC. It is a resistor that, if crossed by a voltage exceeding the supposed one, increases its resistance to limit electricity exceedance. Limitations of this kind of protection concern the low reacting speed, which may progressively stress the components under protection. Therefore, this protection is effective against a limited number of short circuits and it is available only for NPN, PNP, and PUSH-PULL electronics.

### Active protection

This solution is based on a circuit integrated in the electronic output which constantly controls the temperature reached by the element to be protected. In this way, protection is very effective and the reacting speed very high. Moreover, it ensures a constant protection against repetitive and permanent short circuits, that is why is strongly suggested for heavy usages. It is available only for LINE-DRIVER and PUSH-PULL electronics.

# INSTALLATION AND OPERATION PRECAUTIONS

The encoder must be used with respect to its specifications. Encoder is a pulse generator and not a safety device

Assembling and installing personnel must be qualified and carefully follow instructions of technical manual.

Don't expose the device to stress or impacts in order to ensure the correct working otherwise the warranty expires

Make sure that the mechanical coupling of the encoder shaft is designed with the appropriate elastic couplings, especially in the case of accentuated axial or radial movements

Make sure that the environment of use is free of corrosive agents (acids, etc.) or substances that are not compatible with the device

Check the ground connection of the device if it is not possible to provide additional external connection.

Before putting it in operation, verify the voltage range applicable to the device and protect it from exceeding the stated technical specifications.

Connect power supply and signals cables in order to avoid capacitive or inductive interferences that may cause malfunction of the device.

**Cable wiring must be carried out in a POWER-OFF condition**

**For safety reasons, we strongly recommend to avoid any mechanical or electrical modification. In that case, they will void the warranty**

## Main product warranty terms

Replacements or repairs whether under the warranty or at the customer's expense must be performed in the service department of Eltra Srl or by explicitly authorized personnel. Before sending material for repairing, you must obtain an RGA number from our sales office. During the repair process in our service department, Eltra srl will be authorized to remove all parts that the customer added to the product. Any malfunction due to a failure to observe these usage and installation precautions will lead to the warranty voiding. Repairs will not extend the product warranty. We also exclude compensation for any type of damage or injury due to the use, or suspension of use, of the transducer.

Note: for additional information, refer to the sale terms on our website, [www.eltra.it](http://www.eltra.it), or call our office.
